Titanium nitride (TiN) films are formed in a batch reactor using titanium chloride (TiCl₄) and ammonia (NH₃) as precursors. The TiCl₄ is flowed into the reactor in temporally separated pulses. The NH₃ can also be flowed into the reactor in temporally spaced pulses which alternate with the TiCl₄ pulses, or the NH₃ can be flowed continuously into the reactor while the TiCl₄ is introduced in pulses. The resulting TiN films exhibit low resistivity and good uniformity.
Figure 1
DEPOSITION OF TIN FILMS IN A BATCH REACTOR

REFERENCE TO RELATED APPLICATION

This application claims the priority benefit under 35 U.S.C. §119(e) of U.S. provisional Application No. 60/612,332, filed Sep. 22, 2004.

BACKGROUND OF THE INVENTION

This invention relates generally to semiconductor fabrication and, more particularly, to forming titanium nitride films.

For various reasons, including low electrical resistance, good thermal stability and good diffusion barrier properties, there are numerous applications for titanium nitride (TiN) in the fabrication of integrated circuits. Exemplary applications include use as a contact or barrier layer and as an electrode in electrical devices, such as transistors. The properties of TiN, however, are closely dependent on processing and deposition parameters. Thus, the suitability and desirability of deposited TiN for a particular application can depend on the availability of a deposition process able to form TiN with desired properties, e.g., high uniformity and low resistivity. As a result, research into the development of new TiN deposition processes is on-going.

For example, the Low Pressure Chemical Vapor Deposition (LPCVD) of TiN films in a hot wall furnace has recently been described by N. Ramanuja et al. in Materials Letters, Vol. 57 (2002), pp. 261-269. The reach of Ramanuja et al. is limited, however, as Ramanuja et al. investigated 100 mm wafers, rather than industry standard 200 mm and 300 mm wafers. Given the sensitivity of TiN films to deposition conditions, a need still remains for a process that is able to deposit TiN films with good uniformity and low resistivity on industry size wafers, such as 200 mm or 300 mm wafers.

In addition to being able to form acceptable TiN films, it is desirable for the deposition temperature of the TiN deposition process to be relatively low, thereby increasing flexibility for integrating the deposition process with other processes and structures. For example, reducing deposition temperatures to the 400-500°C range would allow the films to be used in conjunction with multi-level aluminum or copper metallization.

It has been found, however, that a reduction in the deposition temperature results in the incorporation of significant amounts of chlorine in the TiN film and results in a substantial increase in resistivity, which is undesirable. See J. T. Hillman, Microelectronic Engineering, Vol. 19 (1992), pp. 375-378. To reduce the resistivity and the chlorine content of the film, Hillman discloses a single wafer deposition process followed by a post-deposition anneal. Undesirably, however, such a process requires an additional processing step and also limits throughput by using single wafer processing.

Accordingly, there is a need for an economical, relatively high throughput process for depositing TiN films having good uniformity and low resistivity.

SUMMARY OF THE INVENTION

According to one aspect of the invention, a method is provided for forming a titanium nitride film. The method comprises providing a plurality of semiconductor substrates in a reaction chamber of a vertical furnace which can accommodate 25 or more substrates. A titanium precursor is flowed into the chamber in temporally separated pulses and a nitrogen precursor is flowed into the chamber.

According to another aspect of the invention, a process for depositing a titanium nitride film is provided. The process comprises chemical vapor deposition titanium nitride on a substrate in a reaction chamber by exposing the substrate to a nitrogen precursor and to a titanium precursor. One of the nitrogen precursor and the titanium precursor is flowed into the chamber in temporally spaced pulses, while the other of the nitrogen precursor and the titanium precursor is continuously flowed into the chamber during and between the temporally spaced pulses.

According to another aspect of the invention, a batch reactor is provided. The reactor comprises a reaction chamber configured to accommodate 25 or more semiconductor substrates. The reaction chamber has a gas inlet. The reactor also comprises a gas delivery system programmed to deliver titanium chloride through the inlet and into the reaction chamber in temporally separated pulses.

According to another aspect of the invention, a batch reactor is provided. The reactor comprises a vertically extending reaction chamber configured to accommodate a plurality of vertically spaced semiconductor substrates. The chamber has a top end and a bottom end. The reactor also comprises a purge gas injector accommodated inside the chamber. The purge gas injector extends upwardly from proximate the bottom end of the reactor and has an opening to the reaction chamber proximate the top end of reaction chamber. The purge gas injector is connected to a feed for purge gas and is configured to expel substantially all purge gas flowing through the purge gas injector out of the opening. At least one reactant gas injector is accommodated in the reaction chamber. The reactant gas injector extends substantially over a height of the chamber and is connected to a process gas delivery system. The process gas delivery system is configured to deliver two process gases to the reaction chamber, one process gas through the at least one injector. The reactor also comprises a gas exhaust proximate the bottom end of the reaction chamber.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be better understood from the Detailed Description of the Preferred Embodiments and from the appended drawings, which are meant to illustrate and not to limit the invention, and wherein:

FIG. 1 illustrates an exemplary furnace for use with preferred embodiments of the invention;

FIG. 2 illustrates an exemplary liquid delivery system for use with preferred embodiments of the invention;

FIG. 3 is a graph showing film thickness results at different vertical substrate positions for a batch of semiconductor substrates processed at two different temperatures in accordance with one preferred embodiment of the invention;
FIG. 4 is a graph showing film resistivity results at different vertical substrate positions for the semiconductor substrates of FIG. 3.

FIG. 5 is a graph illustrating the timing of the flow of reactants, in accordance with another embodiment of the invention.

FIG. 6 is a graph showing film thicknesses and resistivities as a function of the duration of the flow of TiCl$_4$ for each TiCl$_4$ pulse into a reaction chamber; and

FIG. 7 illustrates another exemplary furnace for use with preferred embodiments of the invention; and

FIG. 8 illustrates an additional exemplary furnace for use with preferred embodiments of the invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

It has been found that uniform and low resistivity TiN films can be deposited in a batch reactor by periodically introducing, or pulsing, one or more precursors into the reaction chamber of the reactor. Preferably, the TiN films are formed using stable titanium and nitrogen precursors, i.e., precursors which are not radicals or a plasma. More preferably, titanium tetrachloride (TiCl$_4$) and ammonia (NH$_3$) are used as the titanium and nitrogen precursors, respectively. Both precursors (e.g., TiCl$_4$ and NH$_3$) are alternately pulsed into the reaction chamber or only one precursor is pulsed while the other precursor is flowed continuously into the reaction chamber. In some preferred embodiments, the titanium precursor, e.g., TiCl$_4$, is pulsed into the reaction chamber while the nitrogen precursor, e.g., NH$_3$, is flowed continuously into the chamber.

The deposition advantageously can be performed at a temperature of less than about 600°C and, more preferably, at less than about 500°C, C, e.g., about 450-500°C. Thus, the deposition is compatible with other processes such as multi-level aluminum or copper metallization. In addition, the deposition can advantageously be used to deposit films on industry standard 200 mm and 300 mm wafers.

Preferably, the deposition is performed in a batch reactor configured or programmed to deliver one or more precursors in temporally separated pulses. The batch reactor preferably has a vertically extending reaction chamber which accommodates substrates vertically separated from each other, with major faces of the substrates oriented horizontally. Preferably, the reaction chamber accommodates 25 or more and, more preferably, 50 or more substrates. The illustrated vertical furnace, discussed below, is adapted to support 100-125 substrates.

In some preferred embodiments of the invention, a stack of vertically-spaced substrates, e.g., semiconductors wafers, is accommodated in a batch reaction chamber and temporally separated pulses of the titanium and nitrogen precursors, such as TiCl$_4$ and NH$_3$, are supplied to the reaction chamber alternately and sequentially in an atomic layer deposition of TiN. The deposition rate of the TiN has been found to be particularly sensitive to variations in the gas partial pressure of NH$_3$. As a result, NH$_3$ is preferably flowed into the chamber using a gas injector having vertically distributed holes to allow an even distribution of the NH$_3$. Preferably, each reactant is removed, e.g., by purging with an inert gas or evacuating the reaction chamber, before introduction of the other reactant. The duration of each of the pulses is about 60 seconds or less and, more preferably, about 30 seconds or less and, most preferably, about 15 seconds or less.

In other preferred embodiments, the nitrogen precursor, e.g., NH$_3$, is continuously supplied to the reaction chamber and only the titanium precursor, e.g., TiCl$_4$, is supplied pulse-wise. Advantageously, such a deposition scheme allows an increased deposition rate per reactant pulse without losing film quality, in comparison to a scheme in which both TiCl$_4$ and NH$_3$ are alternately pulsed. By continuously flowing one precursor, more than one monolayer of TiN is typically deposited per TiCl$_4$ pulse. In addition, where the titanium precursor pulses are relatively short, the deposited titanium-containing films are effectively nitrided by the nitrogen precursor flow between the titanium precursor pulses. Thus, high quality, low resistivity and uniform TiN films can be obtained at relatively low deposition temperatures of preferably less than about 600°C C, and, more preferably, less than about 500°C C, e.g., about 450°C. Preferably, the pulse duration is about 60 seconds or less, more preferably, about 30 seconds or less and, most preferably, about 15 seconds or less.

Advantageously, high quality titanium nitride films can be formed in accordance with the preferred embodiments. For example, the thicknesses of deposited titanium nitride films can vary by less than about 3 nm between substrates in a batch of substrates, and the resistivity can vary by less than about 5 µΩcm. Moreover, the films can be formed having a low resistivity of about 220 µΩcm or less.

Reference will now be made to the Figures, in which like numerals refer to like parts throughout.

With reference to FIG. 1, the illustrated reactor 10 is a vertical furnace reactor, which accommodates substrates 40 vertically separated from one another and which has benefits for efficient heating and loading sequences. Examples of suitable vertical furnaces are the A400™ and A412™ vertical furnaces, commercially available from ASM International, N.V. of Bilthoven, the Netherlands. It will be understood, however, that while preferred embodiments are presented in the context of a vertical batch furnace, the principles and advantages disclosed herein will have application to other types of reactors, some of which are further discussed below.

With continued reference to FIG. 1, a tube 12 defines a reaction chamber 20 in the interior of the vertical furnace or reactor 10. The lower end of the tube 12 terminates in a flange 90, which mechanically seals the chamber 20 by contact with a lower support surface 14. Process gases can be fed into the reaction chamber 20 through a gas inlet 22 at the top of the chamber 20 and evacuated out of the chamber 20 through a gas outlet 24 at the bottom of the chamber 20. The reaction chamber 20 accommodates a wafer boat 30 holding a stack of vertically spaced substrates or wafers 40.

The process tube flange 90 can be maintained at an elevated temperature to avoid condensation of process gases on it. It will be appreciated that the elevated temperature can
vary from process to process and is preferably chosen based upon the identities of the process gases. Regulation of the temperature of the flange 30 can be achieved by providing it with electrical heaters and a water-cooling system. The water-cooling is desired primarily to avoid overheating of the flange 30 during unloading of a batch of hot wafers 40.

[0034] Various systems can be used to supply reactants or precursors to the reaction chamber 20 (FIG. 1). For example, where the precursor is a gas, it can be flowed directly from a gas source to the chamber 20. The timing and rate of the flow of the gas can be controlled by, e.g., mass flow controllers, as known in the art.

[0035] Where the precursor, such as TiCl₄, is stored as a liquid, a bubbler can be used to supply the precursor to the chamber in which gaseous form. The timing and rate of flow of such a precursor can be regulated by controlling the flow of carrier gas through the liquid in the bubbler and by controlling the temperature of the liquid. It will be appreciated that the quantity of the liquid precursor carried by the carrier gas increases with increasing temperature.

[0036] Another exemplary system for controlling the flow of liquid precursors, such as TiCl₄, is shown schematically in FIG. 2. The liquid precursor is stored in a container 50. Liquid flow control is used to regulate the amount of the liquid precursor flowing into the reactor 10 by regulating the flow of the liquid into an evaporator or vaporizer 60. After being vaporized, well-separated pulses of a precursor can be generated and flowed into the reaction chamber 20 using a valve system 70 comprising valves 80, shown in the upper section of FIG. 2. Preferably, the valves 80 of the valve system 70 are operated at elevated temperatures and have no or minimal dead volume, to provide good separation between the flow of different reactants. Such a valve system is described in further detail in U.S. patent application Ser. No. 10/864,260, filed Jun. 9, 2004, the entire disclosure of which is incorporated herein by reference.

[0037] With reference to FIGS. 3-6, the deposition results of various deposition schemes discussed above were investigated using TiCl₄ and NH₃ as reactants. The depositions were performed in an A400™ or A412™ vertical furnace from ASM International, N.V., of Biltoven, the Netherlands, schematically illustrated in FIG. 1. Wafers 40 having a diameter of 200 mm were supported on the wafer boat 30 in the furnace 10.

[0038] The wafer spacing on the wafer boat 30 was varied depending upon the precursor pulse scheme. For experiments in which TiCl₄ and NH₃ were alternately pulsed into the reaction chamber 20, the vertical spacing of the 200 mm diameter wafers was about 4.76 mm and the total number of wafers was 125. It will be appreciated that wafers 40 at the top and bottom of the wafer boat 30 are typically not used for further processing. Rather, they may be used for testing and/or are not further processed due to sub-optimal deposition results at the extremes of the reaction chamber 20. Thus, out of a total of 125 wafers, 100 wafers are typically “product wafers” which are to be further processed for completion of integrated circuits.

[0039] For experiments in which one precursor was pulsed while a continuous flow of the other precursor was maintained, the spacing of the 200 mm wafers 40 was twice as large as in experiments where both precursors were alternately pulsed. Thus, the spacing was about 9.54 mm. This resulted in a total load size of 63 wafers and a 50 wafer product load size.

[0040] In some experiments a bubbler was used to deliver TiCl₄ vapor to the reaction chamber 20. The flow of TiCl₄ vapor to the reaction chamber 20 was controlled by controlling the temperature of the TiCl₄ container (not shown) connected to the inlet 22 (FIG. 1). A flow of 250 scm N₂ carrier gas was bubbled through the TiCl₄ container. In most experiments the TiCl₄ container was controlled at about 28°C. In other experiments, the system schematically shown in FIG. 2 was used for controlling the flow of liquid TiCl₄ through an evaporator 60 and for pulsing the TiCl₄.

[0041] During processing, as discussed above, the process tube flange 90 (FIG. 1) can be maintained at an elevated temperature, preferably above 120°C, preferably about 180-200°C, to avoid condensation of material on the flange 90.

[0042] In atomic layer deposition experiments where both precursors were alternately pulsed, the pulse sequence and timing was as follows:

<table>
<thead>
<tr>
<th>Precursor</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>TiCl₄ pulse</td>
<td>15 sec.</td>
</tr>
<tr>
<td>N₂ purge</td>
<td>17 sec./5 tim</td>
</tr>
<tr>
<td>NH₃ pulse</td>
<td>30 sec./1 tim</td>
</tr>
<tr>
<td>N₂ purge</td>
<td>17 sec./5 tim</td>
</tr>
</tbody>
</table>

[0043] The cycle time was 79 seconds and the total recipe time was 18 hours and 30 minutes. Accounting for 1 hour of the recipe time as overhead in which deposition did not occur, the deposition time was 17 hours and 30 minutes. A total of 795 cycles of deposition by alternating precursor flows was performed. The depositions were performed at substrate temperatures of 450°C and 600°C. At a deposition temperature of 450°C, about 0.029 mm of TiN was deposited per cycle, resulting in a deposited film thickness of about 23 nm. Notably, the deposited thickness per cycle is less than 1 Å/cycle (0.1 nm/cycle), which is typical of atomic layer deposition (ALD) processes.

[0044] The thickness results are shown in FIG. 3 and the resistivity results are shown in FIG. 4. Advantageously, at the lower 450°C deposition temperature, the average film thickness across a wafer was found to be exceptionally uniform from wafer to wafer, varying less than about 3 nm among the various wafers of a batch of wafers. At this temperature, the average resistivity of the films was also found to be advantageously uniform, varying less than about 5 μΩcm across the various wafers in the batch.

[0045] In other experiments, pulsed CVD process runs, in which a continuous flow of NH₃ was fed into the reaction chamber and TiCl₄ was pulsed, were performed. FIG. 5 shows the tube pressure, flow rate and pulse timing for each precursor. The deposition temperature was 450°C, the TiCl₄ bubbler temperature was 28°C, and the time between TiCl₄ pulses was 4 minutes. The number of pulses was chosen such that the total TiCl₄ exposure time amounted to 15 minutes. Thus, for a 60 second TiCl₄ pulse time the total number of pulses was 15, for a 30 second pulse time the total number of pulses was 30, and for a 15 second pulse time the
total number of pulses was 60. The NH₃ flow was constant at about 0.2 slm during processing.

For the deposition scheme of FIG. 5, FIG. 6 shows the effects of pulse time on film thickness and resistivity. While longer pulse times would be expected to increase or possibly not affect the thickness of the deposited film in cases where the total TiCl₄ exposure time was unchanged, it was unexpectedly found that pulse times longer than about 30 seconds actually caused a decrease in average film thickness from about 23.5 nm to about 23 nm. Even more unexpectedly, the average resistivity of the deposited film was strongly dependent on pulse times. In particular, film resistivity increased from about 220 μΩcm for TiCl₄ pulse durations of about 15 seconds to about 520 μΩcm for TiCl₄ pulse durations of about 60 seconds. Thus, shorter pulse times advantageously allowed deposition of TiN films with reduced resistivity, e.g., about 220 μΩcm or less.

In addition, the cycle duration can be selected to give a desired TiN film resistivity. For example, resistivities of about 520 μΩcm to about 220 μΩcm can be achieved by appropriately adjusting the TiCl₄ pulse time between about 15 seconds and about 60 seconds, or the duration of each cycle of process gases can be adjusted between about 1 minute and about 10 minutes. In the exemplary process of FIG. 5, the cycle duration was about 5 minutes (60 second TiCl₄ pulse time×4 minutes between TiCl₄ pulses).

As noted above, process gases can be introduced into the chamber 20 in various ways. For example, in the reactor illustrated in FIG. 1, all gases are introduced into the interior 20 of the reactor 10 at the top, via the top inlet 22, and exhausted at the bottom of the reactor 10, via the exhaust 24.

In other embodiments, a more even distribution of the process gases can be achieved over the length of the tube by using multiple hole injectors for introduction of process gases into the reactor. Suitable multiple hole injectors are disclosed in U.S. Pat. No. 6,746,240, issued Jun. 8, 2004, and U.S. patent application Publication No. 2003/0111013 A1, the entire disclosures of which are incorporated by reference herein. Alternatively, less spacious and cylindrical multiple hole injectors can be used. Such injectors can have, e.g., a diameter of about 25 mm and holes of about 1 mm diameter. In some preferred embodiments, multiple hole injectors are preferably mounted on or beneath the flange 90 at the lower end of the reaction chamber 20 and point upwardly.

A multiple hole injector is preferably not used to introduce a purge gas, however, because the top part of the reaction chamber 20 may be not effectively purged by an injector that only extends part way up the height of the chamber 20. Preferably, a purge gas is introduced into the chamber 20 at the chamber end that is opposite to the exhaust end, so that the purge gas flows through all regions of the reaction chamber 20 after entry and before being exhausted.

Another exemplary reactor set-up is shown in FIG. 7. In this design, the process tube 100 is closed at the top. An advantage of this design is that the process tube 100 is simpler in construction and eventual problems with the gas-tightness and the thermal isolation of the top inlet 22 (FIG. 1) can be prevented. All gases in this set-up are introduced through gas injectors 110, of which two are shown. Preferably, separate injectors 110 are used for each gas. In the case of TiN deposition with TiCl₄ and NH₃, one injector 110 is used for each of the process gases. These injectors 110 are preferably multiple hole gas injectors having holes distributed over the height of the tube 100, as discussed above.

An additional injector 110 can be used for a purge gas, preferably an inert gas such as nitrogen gas. The injector 110 for the purge gas is preferably a tube with an open end at the top and without gas discharge holes in its sidewall, so that all the purge gas is discharged at the top of the reaction chamber 120. FIG. 8 illustrates a reactor 10 having three vertically extending injectors, 110a, 110b and 110c. The injectors 110a, 110b and 110c each have an inlet 140a, 140b, and 140c, respectively, for connecting to one or more gas feeds. The injector 110b opens at its top end 112 to allow purge gas to flow downward through the reactor 10 and to exit out the exhaust 24 at the bottom of the reactor 10. In other embodiments, the exhaust 24 can be at the top of the reaction chamber 120 and the purge gas can be discharged at the bottom of the reaction chamber 120. In yet other embodiments, a reaction chamber configuration having an outer process tube and an inner liner can be used. Gas flows in an upward direction inside the liner to the top of the chamber and flows in a downward direction toward an exhaust in a space between the outer surface of the liner and an inner surface of the process tube. The multiple hole injectors are placed inside the liner and a purge gas injector may not be needed. An example of such a reaction chamber configuration is disclosed in U.S. patent application Publication No. 2003/0111013 A1, the entire disclosure of which is incorporated herein by reference.

Advantageously, using such multiple hole gas injectors, the evenness of gas distribution into the reaction chamber can be improved, thereby improving the uniformity of deposition results.

For example, in experiments in which TiN films were formed by continuous CVD, by continuously flowing TiCl₄ and NH₃ into a reaction, it was found that the deposition rate of the TiN films did not vary significantly with the partial pressure of the TiCl₄. On the other hand, the deposition rate appeared to be approximately proportional to the partial pressure of the NH₃. For depositing uniform films, these experiments indicate that the mode of introduction and distribution of NH₃ inside the reaction chamber is more important than that for TiCl₄, whether or not NH₃ is pulsed into the chamber, e.g., whether or not NH₃ is used in an ALD or pulsed CVD process. As a result, NH₃ is preferably discharged into the reaction chamber in a manner that maximizes the evenness of the distribution of the gas into the chamber. NH₃ is preferably discharged into the vertical furnace reaction chamber in a vertically distributed manner, e.g., through a multiple hole injector having a plurality of vertically spaced apart holes, such as those discussed above. The injector preferably extends substantially over a height of the chamber, such that the holes of the injector span the vertical height occupied by the substrates. TiCl₄ can also be discharged using the multiple hole injector, or it can be discharged at a feed end of the reaction chamber (FIG. 1).
EXAMPLE

[0055] An exemplary process for pulsed CVD of TiN films using the reactor hardware configuration of FIGS. 7 and 8 and a TiCl4 liquid flow control and evaporation unit according to FIG. 2 will now be given. A liquid flow of 0.35 g/min. TiCl4 into the evaporator was applied. Upstream of the evaporator, a flow of 200 sccm N2 was added to the liquid and downstream of the evaporator an additional flow of 100 sccm N2 was added to the evaporated TiCl4. The TiCl4 pulse time was 1 minute. The TiCl4/N2 mixture was discharged into the reaction chamber through a multiple hole injector having 30 vertically spaced holes with a diameter of 1 mm or less. During the TiCl4 pulse a mixture of 187 sccm NH3 and 200 sccm N2 was discharged into the reaction chamber through a second multiple hole injector having similar design. After the TiCl4 pulse a purge of 1 slm N2 was applied to the TiCl4 injector for 30 seconds, leaving the NH3 and N2 flows through the NH3 injector unchanged. Then, in an NH3 flush step, the NH3 flow was increased to 1 slm for 2 minutes. After the NH3 flush step the NH3 flow was reduced to 187 sccm again and once again the TiCl4 was purged with 1 slm for 30 seconds. After this cycle starts again with a TiCl4 pulse. During all steps, a purge flow of 100 sccm N2 was discharged through the purge gas injector opening proximate a top end of the reaction chamber. The pressure inside the reaction chamber during the TiCl4 pulses was about 500 mTorr and the reaction chamber temperature was about 500 °C. Through 16 cycles, a film having a thickness of 21 mm and a resistivity of 185 μΩcm was deposited.

[0056] It will be appreciated that the hardware set-up of FIGS. 1, 2, 7 and 8, although described here in the context of pulsed CVD and ALD, is equally suitable for use in the context of low pressure chemical vapor deposition (LPCVD). Further, such a hardware set-up can also be utilized for other deposition chemistries such as Al2O3 deposition using trimethyl aluminum (TMA) and H2O as precursors and the deposition of hafnium oxide (HfO2) using hafnium chloride and water as precursors.

[0057] In addition, while the illustrated reactors are shown holding substrates in a vertically-separated manner, the methods described herein can be applied to any batch reactor including, e.g., reactors which hold substrates in a horizontally-separated manner.

[0058] Where both reactants are pulsed, it will be appreciated that pulse times for both reactants can be the same or each can have a different pulse duration. Moreover, whether one or both reactants are pulsed, the duration of the pulses can remain the same throughout a deposition, or can vary over the course of the deposition.

[0059] Accordingly, it will be appreciated by those skilled in the art that various other omissions, additions and modifications may be made to the methods and structures described above without departing from the scope of the invention. All such modifications and changes are intended to fall within the scope of the invention, as defined by the appended claims.

1-45. (canceled)

46. A batch reactor, comprising:

a reaction chamber configured to accommodate 25 or more semiconductor substrates;

a gas inlet into the reaction chamber; and

a gas delivery system programmed to deliver titanium chloride through the inlet and into the reaction chamber in temporally separated pulses.

47. The batch reactor of claim 46, wherein the gas delivery system is configured to deliver a constant flow of ammonia into the reaction chamber.

48. The batch reactor of claim 46, wherein the gas delivery system is configured to deliver an ammonia flow into the reaction chamber in temporally separated pulses.

49. The batch reactor of claim 46, wherein the gas delivery system is configured to deliver an ammonia flow into the reaction chamber through a gas injector comprising a plurality of vertically spaced gas inlets.

50. The batch reactor of claim 46, wherein the gas delivery system comprises a bubbler.

51. The batch reactor of claim 46, wherein the gas delivery system comprises a gas vaporizer.

52. The batch reactor of claim 46, wherein the reaction chamber is configured to accommodate 100 or more substrates.

53. A batch reactor, comprising:

a vertically extending reaction chamber configured to accommodate a plurality of vertically spaced semiconductor substrates, the chamber having a top end and a bottom end;

a purge gas injector accommodated inside the chamber, wherein the purge gas injector extends upwardly from proximate the bottom end of the reactor and has an opening to the reaction chamber proximate the top end of reaction chamber, wherein the purge gas injector is connected to a feed for purge gas and is configured to expel substantially all purge gas flowing through the purge gas injector out of the opening;

at least one reactant gas injector accommodated in the reaction chamber, the at least one reactant gas injector extending substantially a height of the chamber and connected to a process gas delivery system, the process gas delivery system configured to deliver two process gases to the reaction chamber, one process gas through each of the two injectors; and

a gas exhaust proximate the bottom end of the reaction chamber.

54. The batch reactor of claim 53, wherein the purge gas injector only opens proximate a top of the reaction chamber.

55. The batch reactor of claim 53, wherein the reaction chamber has a closed top end and a bottom end which can be opened for introduction of the substrates.

56. The batch reactor of claim 53, wherein the at least one reactant gas injectors is a multiple hole injector having a plurality of vertically spaced-apart holes for discharging gas into the reaction chamber in a vertically distributed manner.

57. The batch reactor of claim 56, comprising two reactant gas injectors, wherein the one of the two reactant gas injectors is in gas communication with a source of NH3 and wherein the gas delivery system is configured to deliver NH3 through the one of the reactant gas injectors.

58. The batch reactor of claim 57, wherein an other of the two reactant gas injectors is in gas communication to a source of TiCl4.

59. The batch reactor of claim 58, wherein the other of the two reactant gas injectors is a multiple hole injector having
a plurality of vertically spaced-apart holes to discharge gas into the reaction chamber in a vertically distributed manner.

60. The batch reactor of claim 58, wherein the gas delivery system is programmed to deliver the TiCl₄ through the injector into the reaction chamber in temporally separated pulses.

61. The batch reactor of claim 53, wherein the reaction chamber is configured to accommodate 25 or more substrates.

62. The batch reactor of claim 61, wherein the reaction chamber is configured to accommodate 50 or more substrates.

63. The batch reactor of claim 62, wherein the reaction chamber is configured to accommodate 100 or more substrates.
